

HRLT vs HRHT: Welch t = +2.11, p = 0.054 (ns); Mann-Whitney p = 0.095 (ns); Cohen d = +0.78 (large effect, but HRHT n=5 is underpowered)
=> HRLT positive lag is larger on average (research→training direction); not significant at $\alpha=0.05$ with n=5 vs 24.

How to read: box = Q1–Q3, bold line = median, diamond = mean, whiskers = 1.5·IQR, dots = individual topics. Lag > 0 = paper side reached non-trivial yearly presence FIRST (research leads training). Lag < 0 = project side reached it first.

DEFINITION (frozen): lag requires BOTH sides to show non-trivial presence in a single year (paper: ≥ 3 docs & $\geq 0.2\%$ of that year's papers; project: ≥ 2 docs & $\geq 0.2\%$ of that year's projects). LRHT (0/10) and LRLT (0/698) never satisfy this in the 2020-2024 corpus, so lag is undefined for them (expected from their low-research quadrant status). The old 12K-pool claim 'LRHT med = -1.5 yr' came from legacy K=307 data and is RETRACTED.
