

Two-level mixed model (projects nested in colleges, random intercept)
ICC = 0.7376 | n = 3231 projects | 39 college groups | exact β , 95% CI, p-values in the table below

How to read: dot = point estimate β , horizontal bar = 95% CI; bar colour: green = *** (p<0.001), red = ** (p<0.01), grey = ns. CI not crossing 0 $\rightarrow$ significant. Advisor covariates use PRE-PROJECT windows [t-3, t-1] over the 2017-2024 OpenAlex pool; unmatched advisors = NA, not zero. Supervised-projects count is STRICTLY PRIOR (year < focal year; v2.0b leak fix — the earlier full-period count included future projects). Advisor research activity BEFORE the project raises alignment (β =+0.0043, ***); supervising MANY projects lowers it (β =−0.0063, ***). Tier dummies are ns after controlling for college context; alignment drifts up over years (β =+0.0031, ***). Sensitivity on n=2,750 high-confidence matches gives the same signs and significance. [Retracted: v0.9 'recent-3y works β =+0.0085, p=4.5e-7' was a data-lineage artifact (3,712 of 3,714 values were zero).]
